An internal combustion engine (ICE) is a heat engine in which the combustion of a fuel occurs with an oxidizer (usually air) in a combustion chamber that is an integral part of the working fluid flow circuit. In an internal combustion engine, the expansion of the high-temperature and high-pressure gases produced by combustion applies direct force to some component of the engine.

The internal combustion engine is not a heat engine, since it relies on internal combustion processes to produce work. However, heat engine models are useful for introducing the idealized cycle parameters that are also used in more complex combustion cycle models, for example, the fuel--air cycle, to be introduced in Chapter 4.
